WP is write protect. Low active
HOLD suspends operation. Low active. Only available when CS is low
CS is chip select. Low active
SCK is SPI clock
SO is output
SI is input
VDD is from 3.0V to 3.6V
Connect pad only to VSS

The DONE, WAKE and RSTn signals are used to implement the watchdog function. The TPL5010-Q1 is programmed to issue a periodic WAKE pulse to a μC which is in sleep or standby mode. After receiving the WAKE pulse, the μC must issue a DONE signal to the TPL5010-Q1 at least 20 ms before the rising edge of the next WAKE pulse. If the DONE signal is not asserted, the TPL5010-Q1 asserts the RSTn signal to reset the μC . A manual reset function is realized by momentarily pulling the DELAY/M_RST pin to VDD.

Layout Note: Decoupling

A multilayer ceramic bypass X7R capacitor of 0.1 μF is recommended

142 Pixel linear optical array
 Pixels are 100um (H) by 47um (W) with a 50um pitch

One sensor to test functionality, and the ability to add external sensors

U4
 MLX75306

PWR: 3.0 to 3.6V, 3.3V typical

JTAG / SWD

The TDI and TDO pins here match with the target's (the STM32's) TDI and TDO pins.

SRST = System Reset
TRST = JTAG specific reset

The series resistors are useful on high-speed traces.
<https://electronics.stackexchange.com/questions/7709/why-put-a-resistor-in-series-with-signal-line>

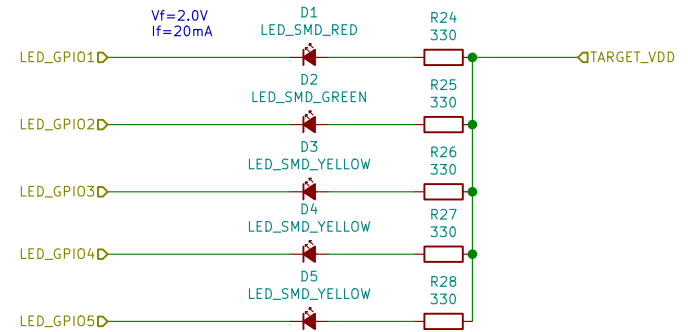

So I'm going with 50 ohm

JTAG
TDI (Test Data In)
TDO (Test Data Out)
TCK (Test Clock)
TMS (Test Mode Select)
TRST (Test Reset) optional.

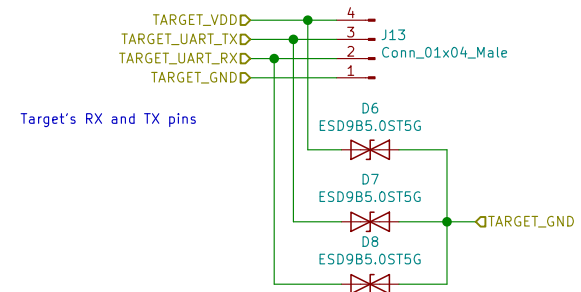

SWD
SWCLK (Clock signal to target CPU)
SWDIO (Bi-directional data pin)
SWO (Serial Wire output) optional

DEBUG LED

D = CAN transmit data input, also called TXD, driver input
R = CAN receive data output, also called RXD, receiver output
Vref = Vcc/2 reference output pin
RS = Mode select, Strong pull down to GND = high speed mode.
Strong pull up to Vcc= low power mode. 10k to 100k to GND = slope control mode. Strong pull down to GND = High Speed

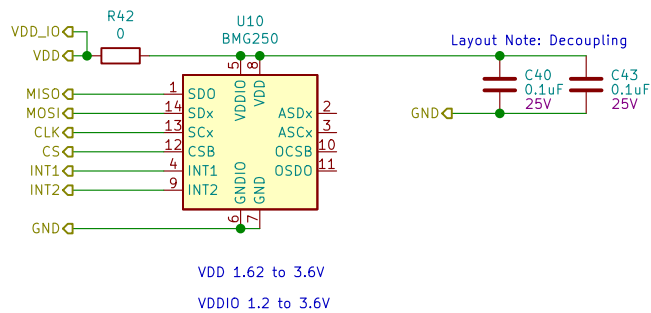

See SN65VD230 Datasheet for layout & more information about split termination

Layout Note: Decoupling
